Rev.00 of: 17/08/2021

Remarks:

This table lists test results from the manufacturer internal laboratory, some of which may be older. The composition of previously tested products may have been changed in the meantime. In the case of various combinations, there is no experience of the behavior in the event of longer exposure to moisture or at higher temperatures. Please contact us if necessary! Weathered substrates often behave differently than new ones in terms of adhesion. On the one hand, loose layers can form on the surface, which worsen the adhesion without undercoating; on the other hand, adhesion groups can arise on the surface due to oxidation, which can produce useful results with otherwise poorly coatable webs (ECB, FPO, TPO). In case of doubt, experiments are therefore always advisable. Customers often want to seal on "wood", "aluminum" or similar. The fact that the surfaces are actually painted or coated is often not known or is not mentioned, therefore, if in doubt, ask or test beforehand. The liability tests were carried out by the manufacturer to the best of his knowledge. However, we cannot completely rule out the possibility that the adhesion properties will change due to modifications to the materials tested as substrates. If a combination of materials tested by the manufacturer has been assessed as good or very good with regard to the adhesive properties, this does not automatically mean that the manufacturer of the substrate material has approved this combination. If in doubt, you should therefore consult Riwega technical department and the manufacturer of material to be coated. For adhesions on liquid plastics from other manufacturers, please also contact our technical department (info@riwega.com).
